INSTRUMENT TITLE: *Malay version of Medical Outcomes Study (MOS) – Social Support Survey*

SOURCE ARTICLE: Saddki, N., Sulaiman, Z., Abdullah, S., Zakaria, N., Mohamad, N., Ab Razak, A., & Zainan Abidin, Z. (2017). Psychometric properties of the Malay version of the Medical Outcomes Study Social Support Survey (MOS-SSS) in a sample of patients with HIV. *Journal of HIV/AIDS & Social Services, 16*(1), 60-74.

POPULATION: Women, men, HIV-positive, adults in Malaysia

RESPONSE OPTIONS: 5-point Likert scale with “1” for none of the time, “2” for a little of the time, “3” for some of the time, “4” for most of the time, and “5” for all of the time.

SCORING: The score for each subscale can be obtained by calculating the average of the scores for each item in the subscale. Alternatively, the summed raw scores of each subscale can be transformed and reported on a scale of 0 to 100. Additionally, an overall functional social support index can be obtained by calculating the average of the scores for all 18 items included in the four subscales and the score for the one additional item. A higher score for an individual subscale or for the overall support index indicates better perceived social support.

SURVEY ITEMS: Please see attached

RELIABILITY INFORMATION: Cronbach’s $\alpha = 0.96$, $r = 0.88$

VALIDITY INFORMATION: Content-related validity was assessed. Known group validity was also assessed using married and unmarried patients. Factor structure was tested and results determined that this scale is supposed to measure emotional/informational support, tangible support, positive social interaction, and affectionate support.
